

# 2D Arrays

# Due this week

---

- **Project 1**

- It's been released, so start working on it
- There will be a mandatory interview grading (will provide more information on Friday)
- Discuss with us regarding any concerns you may have

# 2D Arrays

# Two-Dimensional Arrays

---

- It often happens that you want to store collections of values that have a two-dimensional layout.
- Such data sets commonly occur in financial and scientific applications. Let's look into a few of such scenarios
- An arrangement consisting of *tabular data* (rows and columns of values) is called:  

a ***two-dimensional array***, or a ***matrix***

# The chessboard

# Olympics Medal Count

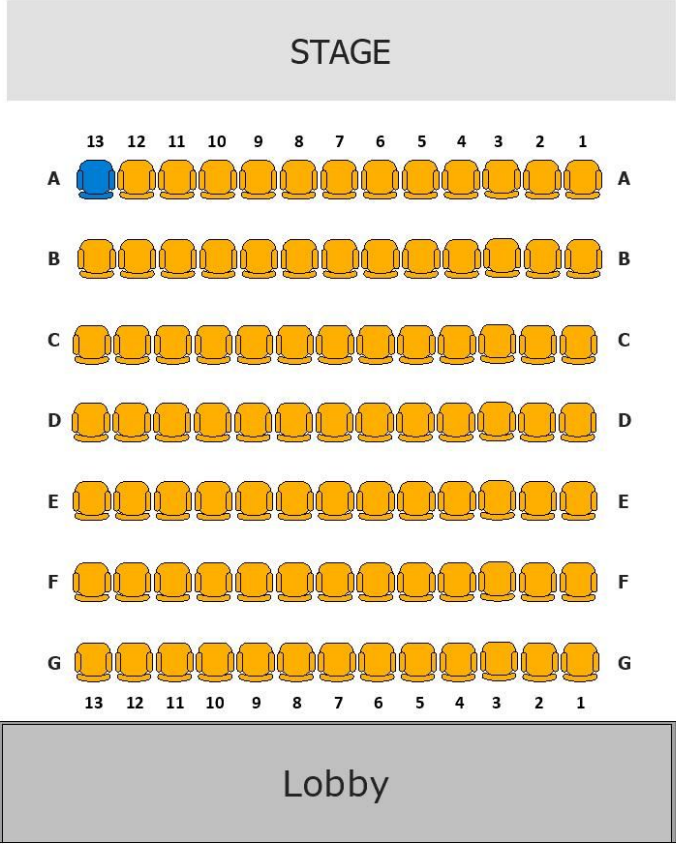

---

## Top 10 performers by total medal count

Rank	Country	Gold	Silver	Bronze	Total
1	 US	39	41	33	113
2	 China	38	32	18	88
3	 ROC	20	28	23	71
4	 Great Britain	22	21	22	65
5	 Japan	27	14	17	58
6	 Australia	17	7	22	46
7	 Italy	10	10	20	40
8	 Germany	10	11	16	37
9	 Netherlands	10	12	14	36
10	 France	10	12	11	33

# A Seat Matrix

---

# How we define 2D arrays

---

C++ uses an array with *two* subscripts to store a *2D* array.

For instance,

```
const int COUNTRIES = 10;  
const int MEDALS = 3;  
int counts[COUNTRIES][MEDALS];
```

An array with 10 rows and 3 columns is suitable for storing our medal count data.

# Initializing 2D arrays

---

Just as with one-dimensional arrays, you ***cannot*** change the size of a two-dimensional array once it has been defined.

You can initialize them.

```
int counts[10][3] =
{
    { 39, 41, 33 },
    { 38, 32, 18 },
    { 20, 28, 23 },
    { 22, 21, 22 },
    { 27, 14, 17 },
    { 17, 7, 22 },
    { 10, 10, 20 },
    { 10, 11, 16 },
    { 10, 12, 14 },
    { 10, 12, 11 }
};
```

# A look at 2D array definition

## Two-Dimensional Array Definition

Diagram illustrating the components of a 2D array definition:

**Element type** points to `int`.

**Rows** points to the first `4` in `data[4][4]`.

**Columns** points to the second `4` in `data[4][4]`.

**Name** points to `data`.

```
int data[4][4] = {  
    { 16, 3, 2, 13 },  
    { 5, 10, 11, 8 },  
    { 9, 6, 7, 12 },  
    { 4, 15, 14, 1 },  
};
```

Optional list of initial values

# Test your understanding

---

- Identify the scenarios where you can use 2D arrays!
  - Movie theatre seat matrix
  - A tic tac toe board
  - Images! How??
  - Educational records
  - Geolocations

*Anything that is represented as a grid is a 2D array!*

# Two-Dimensional Arrays – Accessing Elements

---

Think of this like you're trying to find your seat in a theatre

# Two-Dimensional Arrays – Accessing Elements

---

```
int value = balances[3][4];  
cout << value;
```

```
// change the element  
balances[3][4] = 100;
```

Give the row and the column index of the element you wish to access in square brackets.

# Print 1<sup>st</sup> row elements in a 2D Array

```
[0][0], [0][1], [0][2]
// Print the 1st row:
cout << setw(8) << counts[0][0];
cout << setw(8) << counts[0][1];
cout << setw(8) << counts[0][2];
```

You get the picture of how to print elements now. Like before, provide the row and the column index.

## Top 10 performers by total medal count

Rank	Country	Gold	Silver	Bronze	Total
1	 US	39	41	33	113
2	 China	38	32	18	88
3	 ROC	20	28	23	71

BBC

# Print 1<sup>st</sup> row elements in a 2D Array (using loop)

```
[0][0], [0][1], [0][2]
// Process the 1st row:
for (int j = 0; j < MEDALS; j++)
{
    cout << setw(8) << counts[0][j];
}
```

## Top 10 performers by total medal count

Rank	Country	Gold	Silver	Bronze	Total
1	 US	39	41	33	113
2	 China	38	32	18	88
3	 ROC	20	28	23	71
4	 Great Britain	22	21	22	65
5	 Japan	27	14	17	58
6	 Australia	17	7	22	46
7	 Italy	10	10	20	40
8	 Germany	10	11	16	37
9	 Netherlands	10	12	14	36

# Print all elements in a 2D Array

---

```
for (int i = 0; i < COUNTRIES; i++)
{
    // Process the ith row
    for (int j = 0; j < MEDALS; j++)
    {
        // Process the jth column in the ith row
        cout << setw(8) << counts[i][j];
    }
    // Start a new line at the end of the row
    cout << endl;
}
```

In order to print each element, we need two for loops:

- one to loop over all rows,
- and another to loop over all columns.

# Computing Row and Column Totals

---

- One application is to compute the row and the column totals
  - What information do you need to compute the sum of a row?
  - What about a column?

# Computing Column Totals: Code Example

Column totals:

Let  $j=1$  be the silver column:

Let COUNTRIES=10

Let the 2d array be named as counts

Top 10 performers by total medal count

# Two-Dimensional Array Parameters

---

- Similar to one-dimensional array
  - 1<sup>st</sup> dimension size not given (Provided as second parameter)
  - 2<sup>nd</sup> dimension size IS given
- Example:

```
void displayMedalCount(const char count[][3], int countries)
{
    for (int index1=0; index1 < countries; index1++)
    {
        for (int index2=0; index2 < 3; index2++) {
            cout << p[index1][index2];
        }
        cout << endl;
    }
}
```

# Two-Dimensional Array Parameters

---

- When passing a two-dimensional array to a function, you must specify the number of columns *as a constant* when you write the parameter type, so the compiler can pre-calculate the memory addresses of individual elements.
- This function computes the total of a given row.

```
int getRowTotal(int table[][3], int row)
{
    // Some code here
}

// calling this function (in main function)
int total = getRowTotal(table, 2);
```

# Two-Dimensional Array Parameter Columns Hardwired

---

That function works for only arrays of 3 columns.

If you need to process an array with a different number of columns, like 4, you would have to write ***a different function*** that has 4 as the parameter.

# 2D Arrays

# Unfolding Two-Dimensional Arrays

---

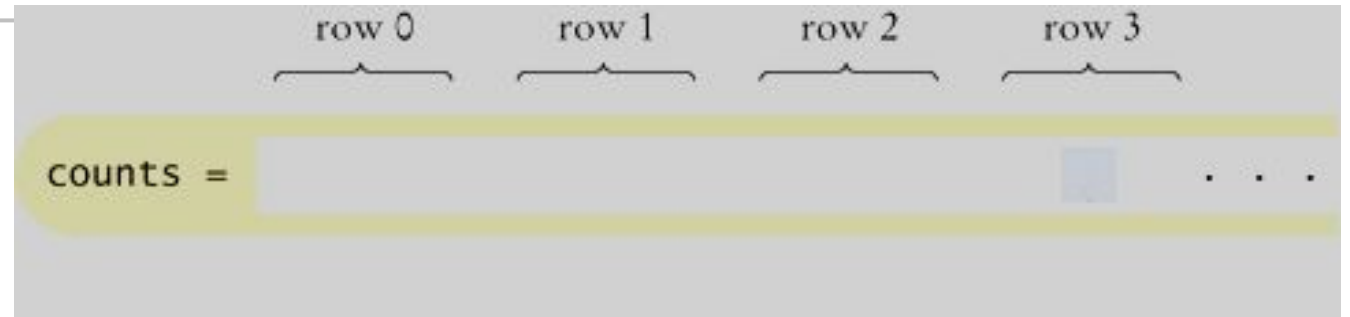

From last class, we mentioned “specify column dimension is mandatory in function parameter for 2d arrays”. Why?

```
void print2D(int array[][5], int rows) {  
    ...  
}
```

# Two-Dimensional Array Storage

What's the reason behind this?

Although the array appears to be two-dimensional, the elements are still stored as a linear sequence.

**counts** is stored as a sequence of rows, each 3 long.

So where is **counts**[3][1]?

The offset (calculated by the compiler) from the start of the array is

***3 x number of columns + 1***

# Two-Dimensional Array Parameters: Rows

---

The **row\_total** function did not need to know the number of rows of the array.

If the number of rows is required, pass it in:

```
int column_total(int table[][COLUMNS], int rows, int col)
{
    int total = 0;
    for (int i = 0; i < rows; i++)
    {
        total = total + table[i][col];
    }
    return total;
}
```

# What are some of it's drawbacks?

---

- The size of an array cannot be changed after it is created.
- You have to get the size right before you define an array
- The compiler needs to know the size in order to build the array, and functions need to be told number of elements in array, and possibly its capacity (and arrays can't hold more than their initial capacity)

# Practice It

---

- Check if the piece at row 4 and column 4 is a bishop

```
if () {  
    cout << "It is a bishop";  
}
```

```
board[4][4] == "bishop"
```

```
board[3][3] == "bishop"
```

```
board[3][3] = "bishop"
```

```
board[4][4] = "bishop"
```

# Practice It

- Show all empty seats in a theatre

```
for (i=0; i<rows; i++) {  
    for (j=0; j<cols; j++) {  
        // check if the seat is  
        // empty  
    }  
}
```

0	0	0	1	1	0	1	1	1	<code>seats[0][7]=1</code>
1	0	1	1	0	0	1	0	1	
2	1	0	0	1	0	1	1	0	
3	0	1	1	1	0	0	0	1	<code>seats[4][6]=0</code>
4	0	0	1	1	0	1	0	0	
5	1	0	1	1	0	0	1	1	
	0	1	2	3	4	5	6	7	<code>seats[5][0]=1</code>
